# STBC08

800 mA standalone linear Li-Ion battery charger with thermal regulation

Datasheet - production data

DFN6 (3x3 mm)

Features

- Programmable charge current up to 800 mA
- No external MOSFET, sense resistors or blocking diode are required
- Complete linear charger for single-cell Li-Ion batteries
- Constant current/constant voltage operation with thermal regulation to maximize charge rate without risk of overheating
- Two charge status output pins
- Charge single-cell Li-Ion batteries directly from USB port
- Preset 4.2 V charge voltage with 1% accuracy
- Charge current monitor for gas gauge
- Automatic recharge
- Undervoltage lockout
- C/10 charge termination
- 25 µA supply current in shutdown mode
- Low battery voltage detection for pre-charge setting
- Soft-start feature limits inrush current
- DFN6 (3x3 mm) package (to improve power dissipation)

Applications

- Cellular phones
- PDAs
- Bluetooth® applications
- Battery-powered devices

Description

The STBC08 is a constant current/constant voltage charger for single-cell Li-Ion batteries. Neither external sense resistor nor blocking diode are required. The STBC08 is designed to work within USB power specifications. An internal block regulates the current when the junction temperature increases, to protect the device when it operates in high power or high ambient temperature conditions. The charge voltage is fixed at 4.2 V, and current limitation can be programmed using a single resistor connected between PROG pin and GND. The charge cycle is automatically terminated when the current, which flows to the battery, is 1/10 of the programmed value. If the external adapter is removed, the STBC08 turns off and a 2 µA current can flow from the battery to the device. The device can be in shutdown mode, reducing the supply current to 25 µA. The device also has a charge current monitor, undervoltage lockout, automatic recharge. The charge termination and input voltage presence are indicated by two separated status pins.

Figure 2. Pin connection (top view)
Table 2. Pin description

Pin	Symbol	Notes
1	BAT	This pin provides an accurate output voltage of 4.2 V and the charge current to the battery. Only 2 µA reverse current can flow to the device when it is in shutdown mode.
2	POWER ON	Open drain. When the STBC08 detects an undervoltage lockout condition or when the external adapter provides an input voltage higher than 7.2 V or less than the battery voltage, POWER ON goes to high impedance state.
3	CHRG	Open drain. This pin goes to low impedance when the STBC08 is in pre-charge or charge mode.
4	GND	Ground pin.
5	PROG	Charge current program, charge current monitor and shutdown pin. The current limitation is programmed using R_{PROG} tolerance of 1% between PROG pin and GND.
6	V_{CC}	Input supply voltage. The input range goes from 4.25 to 6.5 V. If VCC < V_{BAT} + 30 mV the device enters shutdown mode and the sinked I_{BAT} is less than 2 µA.
7	Exposed pad	Connected to GND or left floating.

6 Application information

The STBC08 uses an internal P-channel MOSFET to work in constant current and constant voltage method. It provides up to 800 mA with a final regulated output voltage of 4.2 V ±1% in full temperature range. Neither blocking diode nor sensing resistor are required. The USB port can be used as a power supply voltage.

6.1 Charge cycle

A charge cycle begins when the voltage at the V_{CC} pin rises above UVLO threshold level, R_{PROG} program resistor of 1% is connected between PROG pin and GND pin and when a battery is connected to the charger output. If the battery voltage is below 2.9 V, the charger enters trickle charge mode. In this condition, the device supplies 1/10th of the programmed charge current to keep the battery voltage in a safe level otherwise the life of a battery reduces. If BAT pin voltage is higher than 2.9 V the charger goes to constant current mode. When BAT pin voltage is close to the final float voltage (4.2 V) the device goes to constant voltage mode and the charge current begins decreasing. The charge cycle is over when the current drops 1/10th of the programmed value.

6.2 V_{CC} pin

Input supply voltage is used to supply the device in the range from 4.25 V to 6.5 V voltage. A bypass capacitor of 1 µF is recommended. When V_{CC} value drops below 30 mV of BAT pin voltage, the device goes to shutdown mode, dropping I_{BAT} less than 2 µA.

6.3 POWER ON pin

POWER ON pin is an open drain flag indicating V_{CC} presence, $V_{UVLO} < V_{CC} < 7.2$ V and $V_{CC} > V_{BAT}$. While in high impedance, it indicates that $V_{CC} < V_{UVLO}$, $V_{CC} > 7.2$ V or $V_{CC} < V_{BAT}$. In high impedance status V_{CC} doesn't start the charge cycle.

6.4 CHRG pin

CHRG pin is an open drain flag indicating the status of the charge. When the pin is in low-state, the device charges the battery. If the pin is in high impedance state the charge is over.

Table 6. Flag status values for CHRG pin

POWER ON	CHRG	Description
0	0	Pre-charge mode (trickle charge mode) or charge mode. V_{CC} is higher than V_{UVLO} and R_{PROG} is connected to PROG pin.
0	1[(1)]	Standby mode (charge completed) or shutdown mode (R_{PROG} not connected).
1[(1)]	1[(1)]	Supply is not sufficient.

1. Output pin in high impedance (external pull-up needed).

6.5 PROG pin

Charge current program, charge current monitor and shutdown pin. The charge current is programmed by connecting a resistor of 1%, R_{PROG}, to ground. When the device charges in constant current, the voltage value of this pin is 1.0 V. In other conditions, the voltage on this pin can measure the charge current thanks to the following formula:

Equation 1

$$I_{BAT} = (V_{PROG}/R_{PROG})*1000$$

PROG pin shuts down the device; disconnecting the program resistor from ground, the current of 1 µA flows to pull PROG pin high. If the value of this pin is 1.21 V (shutdown threshold voltage), the device enters shutdown mode and the input supply current drops to 25 µA. Driving this pin to voltage beyond 2.4 V, a current of 35 µA flows to the device from PROG pin.

6.6 Programming charge current

R_{PROG} resistor sets the charge current value. The battery charge current is 1000 times the PROG pin current value. The program resistor and the charge current are calculated according to the following equation:

Equation 2

$$R_{PROG}=1000*V_{PROG}/I_{BAT}$$

The charge current out of BAT pin can be monitored by PROG pin voltage as per below equation:

Equation 3

$$I_{BAT}=(V_{PROG}/R_{PROG})x1000$$

6.7 BAT pin

The charge current output pin provides the battery with charge current and regulates the final float voltage to 4.2 V. An internal resistor is a feedback loop, which compares V_O with the reference.

6.8 Charge termination

A charge cycle is terminated when the final float voltage is reached while the charge current falls 1/10th of the programmed value. The charge is over when PROG pin voltage falls below 100 mV for a time longer than t_{TERM} (~1 ms). The charge current is latched off, the device is in standby mode and the input supply current drops to 200 μA.

6.9 Automatic recharge

The device restarts the charge cycle when the battery voltage falls below 4.05 V to maintain the battery capacity value higher than 80%. During the recharge time, CHRG pin goes to low-state.

6.10 Soft-start

When a charge cycle starts, an internal soft-start circuit minimizes the inrush current.
At starting phase, the charge current ramps from zero to full scale in 100 μs.

6.11 Thermal regulation

An internal thermal feedback loop reduces the output current if the die temperature rises above a present value of approximately 120 °C. This feature protects the device from the excessive temperature and allows the user to push the limits of the power handling the capability of a given circuit board without damaging the device.

6.12 Power dissipation

A good thermal PC board layout should be used to maximize the available output current. The thermal path for the heat generated by IC is from the die to the copper lead frame through the package leads and exposed pad to the PC board copper.

The PC board copper is the heat sink. Footprint copper pads should be as wider as possible and expand out to larger copper areas to spread and dissipate the heat to the surrounding ambient. Feed-through vias to inner or backside copper layers are also useful to improve the overall thermal performance of the device. Other heat sources on the board, not related to the device, have to be considered when a PC board layout is designed because they affect the overall temperature rise and the maximum output current.

6.13 Stability considerations

The STBC08 contains two control loops: the constant voltage and the constant current. The constant voltage loop is stable without any compensation when a battery is connected with low impedance leads. Excessive lead length, however, may add enough parasitic series inductance to require 1 µF bypass capacitor from BAT to GND. Furthermore, a 4.7 µF capacitor with a series resistor (0.2 Ω to 1 Ω) from BAT to GND is required to keep ripple voltage low when the battery is disconnected.

7   Package mechanical data

In order to meet environmental requirements, ST offers these devices in different grades of
ECOPACK® packages, depending on their level of environmental compliance. ECOPACK®
specifications, grade definitions and product status are available at: *www.st.com*.
ECOPACK® is an ST trademark.
